- I. The aim of this short memo is to resolve the linear system of equations using Gauss elimination method.

$$\begin{aligned} C_{L,lin}(\alpha_*) &= a_1 \cdot \alpha_*^3 + b_1 \cdot \alpha_*^2 + c_1 \alpha_* + d_1 \\ C_{L,max} &= a_1 \cdot \alpha_{C_{L,max}}^3 + b_1 \cdot \alpha_{C_{L,max}}^2 + c_1 \alpha_{C_{L,max}} + d_1 \\ C_{L\alpha} &= 3a_1 \alpha_*^2 + 2b_1 \alpha_* + c_1 \\ 0 &= 3a_1 \alpha_{C_{L,max}}^2 + 2b_1 \alpha_{C_{L,max}} + c_1 \end{aligned}$$

Note: The vector of unknowns is: $[a_1, b_1, c_1, d_1]$. The constants are: $C_{L,lin}(\alpha_*)$, $C_{L,max}$, α_* and $\alpha_{C_{L,max}}$

To facilitate the writing of the system of equations, we adopt the following change of variables:

$$[a_1, b_1, c_1, d_1] = [x, y, z, t].$$

The constants α_* , $\alpha_{C_{L,max}}$, $C_{L,lin}(\alpha_*)$, $C_{L,max}$ and $C_{L\alpha}$ are replaced by: a , b , c , d , and e , respectively.

This leads to the following equations:

$$\begin{aligned} c &= x \cdot a^3 + y \cdot a^2 + za + t \\ d &= x \cdot b^3 + y \cdot b^2 + zb + t \\ e &= 3xa^2 + 2ya + z \\ 0 &= 3xb^2 + 2yb + z \end{aligned}$$

We can represent this system in augmented matrix form:

$$\begin{aligned} \begin{matrix} R_1 \\ R_2 \\ R_3 \\ R_4 \end{matrix} &\rightarrow \left(\begin{array}{cccc|c} 1 & a & a^2 & a^3 & t \\ 1 & b & b^2 & b^3 & z \\ 0 & 1 & 2a & 3a^2 & y \\ 0 & 1 & 2b & 3b^2 & x \end{array} \right) = \begin{pmatrix} c \\ d \\ e \\ 0 \end{pmatrix} \\ \begin{matrix} R_1 \\ R_2 - R_1 \\ R_3 \\ R_4 \end{matrix} &\rightarrow \left(\begin{array}{cccc|c} 1 & a & a^2 & a^3 & t \\ 0 & b - a & b^2 - a^2 & b^3 - a^3 & z \\ 0 & 1 & 2a & 3a^2 & y \\ 0 & 1 & 2b & 3b^2 & x \end{array} \right) = \begin{pmatrix} c \\ d - c \\ e \\ 0 \end{pmatrix} \\ \begin{matrix} R_1 \\ R_2 \\ R_3(a - b) + R_2 \\ R_4(a - b) + R_2 \end{matrix} &\rightarrow \left(\begin{array}{cccc|c} 1 & a & a^2 & a^3 & t \\ 0 & b - a & b^2 - a^2 & b^3 - a^3 & z \\ 0 & 0 & (a - b)^2 & 3a^2(a - b) + b^3 - a^3 & y \\ 0 & 0 & -(a - b)^2 & 3b^2(a - b) + b^3 - a^3 & x \end{array} \right) = \begin{pmatrix} c \\ d - c \\ e(a - b) + d - c \\ d - c \end{pmatrix} \\ \begin{matrix} R_1 \\ R_2 \\ R_3 \\ R_4 + R_3 \end{matrix} &\rightarrow \left(\begin{array}{cccc|c} 1 & a & a^2 & a^3 & t \\ 0 & b - a & b^2 - a^2 & b^3 - a^3 & z \\ 0 & 0 & (a - b)^2 & 3a^2(a - b) + b^3 - a^3 & y \\ 0 & 0 & 0 & 3(b^2 + a^2)(a - b) + 2b^3 - 2a^3 & x \end{array} \right) = \begin{pmatrix} c \\ d - c \\ e(a - b) + d - c \\ e(a - b) + 2(d - c) \end{pmatrix} \end{aligned}$$

We ultimately derive the value of x from the last equation of the system:

$$x = \frac{e(a-b) + 2(d-c)}{3(b^2 + a^2)(a-b) + 2b^3 - 2a^3} = \frac{e(a-b) + 2(d-c)}{(a-b)^3}$$

From the value of x , we can backtrack to obtain the values of the other variables y , z , and t .

Alternatively, we can subtract the two equations from one another to find the value of y :

$$e = 3xa^2 + 2ya + z$$

$$0 = 3xb^2 + 2yb + z$$

From these equations, we can derive:

$$e = 3x(a^2 - b^2) + 2y(a - b)$$

Thus, the value of y is given by:

$$y = \frac{e - 3x(a^2 - b^2)}{2(a - b)} = \frac{e - 3 \frac{e(a-b) + 2(d-c)}{(a-b)^3} (a^2 - b^2)}{2(a - b)}$$

Next, we can derive the formula for z from the equation: $0 = 3xb^2 + 2yb + z$

$$z = -2yb - 3xb^2$$

Substituting for y :

$$z = -2b \frac{e - 3 \frac{e(a-b) + 2(d-c)}{(a-b)^3} (a^2 - b^2)}{2(a - b)} - 3b^2 \frac{e(a-b) + 2(d-c)}{(a-b)^3}$$

Finally, for the variable t , we can use the equation:

$$c = x \cdot a^3 + y \cdot a^2 + za + t$$

Rearranging gives us:

$$t = c - za - y \cdot a^2 - x \cdot a^3$$

Thus, we have:

$$t = c + 2ab \frac{e - 3 \frac{e(a-b) + 2(d-c)}{(a-b)^3} (a^2 - b^2)}{2(a - b)} + 3ab^2 \frac{e(a-b) + 2(d-c)}{(a-b)^3} - a^2 \frac{e - 3 \frac{e(a-b) + 2(d-c)}{(a-b)^3} (a^2 - b^2)}{2(a - b)} - a^3 \frac{e(a-b) + 2(d-c)}{(a-b)^3}$$

However, due to the complexity of the expressions, it is impractical to write them out in their entirety. For the

sake of simplification, the final solution can be expressed as:
$$\begin{bmatrix} x \\ y \\ z \\ t \end{bmatrix} = \begin{bmatrix} \frac{2(c-d) - e(a-b)}{(b-a)^3} \\ \frac{e - 3x(a^2 - b^2)}{2(a-b)} \\ -2by - 3b^2x \\ c - az - a^3x - a^2y \end{bmatrix}$$

II. now, let's try to resolve the linear system of equations using substitution method:

$$c = x \cdot a^3 + y \cdot a^2 + za + t \dots (1)$$

$$d = x \cdot b^3 + y \cdot b^2 + zb + t \dots (2)$$

$$e = 3xa^2 + 2ya + z \dots (3)$$

$$0 = 3xb^2 + 2yb + z \dots (4)$$

$$(1)-(2): c - d = x \cdot (a^3 - b^3) + y \cdot (a^2 - b^2) + z(a - b) \dots (5)$$

$$(3)-(4): e = 3x(a^2 - b^2) + 2y(a - b) \dots (6)$$

$$y = \frac{e - 3x(a^2 - b^2)}{2(a - b)}$$

$$y = \frac{e}{2(a - b)} - \frac{3}{2}(a + b)x$$

$$(3): z = -3xb^2 - 2yb = -3xb^2 - 2b \left[\frac{e}{2(a - b)} - \frac{3}{2}(a + b)x \right] = \frac{-be}{a - b} + 3b(a + b)x - 3xb^2$$

$$z = \frac{-be}{a - b} + 3abx$$

We substitute the values of y and z into Equation (5):

$$c - d = x \cdot (a^3 - b^3) + \left[\frac{e}{2(a - b)} - \frac{3}{2}(a + b)x \right] \cdot (a^2 - b^2) + \left[\frac{-be}{a - b} + 3abx \right] (a - b)$$

$$-be + 3abx(a - b) + \frac{e}{2}(a + b) - \frac{3}{2}x(a + b)^2(a - b) + x(a^3 - b^3) = c - d$$

$$2x \left[3a^2b - 3ab^2 - \frac{3}{2}(a - b)(a + b)^2 + a^3 - b^3 \right] = 2c - 2d - ea + eb$$

$$x \left[\frac{3}{2}a^2b - \frac{3}{2}ab^2 - \frac{1}{2}a^3 + \frac{1}{2}b^3 \right] = 2c - 2d - ea + eb$$

we obtain the value of x :

$$x = \frac{e(a - b) + 2(d - c)}{(a - b)^3}$$

We follow the same procedure described previously to find the values of y , z , and t .
